The electrical signature of ventricular activation on the ECG – the QRS complex – contains a wealth of information regarding not only the nature of the rhythm but its context and origin. This has important implications for diagnosis and appropriate direction of therapy.

Is it really ventricular tachycardia?

What is the setting of, or substrate for, the arrhythmia?

Why are there differences in the QRS complex during different forms of VT in the same person?

From where in the ventricles is the QRS arising/exiting?
